

2-HECTARE TUNNEL

The 2 ha Tunnel Barn is a large-scale, continuous-flow curing system engineered for high-throughput and precision drying. It operates on a controlled thermal expansion principle where increasing internal temperature generates a gradual pressure rise (~0.57 hPa/day), creating a defined pressure gradient between the barn interior and ambient atmosphere. This differential drive directed airflow through the curing tunnel, enhancing moisture removal efficiency. As velocity increases toward outlet zones, drying rates intensify, requiring staged control to prevent early-stage over-drying or green fixation. The system integrates trolley-based leaf transport for continuous loading and unloading, alongside electric heat exchangers and forced-air circulation systems. This automation reduces labour demand while ensuring uniform, high-quality curing consistency at scale.
